

At 120 sessions the design separates an out-of-sample R^2 from zero only once it exceeds 0.113, roughly 11 times the largest effect the literature reports; 15,126 sessions would be needed for 0.01. Widening the cross-section raises the independent rows a session carries from 1.48 only as far as 1.76, a standard-error gain of 9% for unlimited names.
