

The best of six models, placed in its own null distribution

99.7% of 10,000 recentred replications land at or above the observed maximum, so the Reality Check p-value is 0.9970. The null distribution sits above zero because it is the distribution of a maximum over six candidates: that offset is the data-snooping correction made visible. The observed maximum is itself negative, so the best candidate loses to the null before any correction is applied.
